Abstract

Due to the frequent occurrence of cyclopentane subunits in bioactive compounds, the development of efficient catalytic asymmetric methods for their synthesis is an important objective. In this report, we introduce a new family of chiral nucleophilic catalysts, biphenyl-derived phosphepines, and we apply them to an enantioselective variant of a useful [4+1] annulation first described by Tong. A range of one-carbon coupling partners can be employed, thereby generating cyclopentenones that bear a fully substituted stereocenter (either all-carbon or heteroatom-substituted (sulfur and phosphorus)). Stereocenters at the other four positions of the cyclopentane ring can also be introduced with good stereoselectivity. An initial mechanistic study indicates that phosphine addition to the electrophilic four-carbon coupling partner is not the turnover-limiting step of the catalytic cycle.

Keywords

annulation; asymmetric catalysis; atropisomerism; organocatalysis; phosphane

During the past decade, chiral tertiary phosphines have increasingly been employed not only as ligands in transition-metal-catalyzed reactions,^[1] but also as enantioselective nucleophilic catalysts for a broad spectrum of useful transformations.^[2,3] Studies by our lab and by others have established that 1,1'-binaphthyl-derived phosphepines (e.g., **1**) are effective for a diverse array of interesting processes;^[4,5,6] in contrast, to the best of our knowledge, there have been no applications of axially chiral biphenyl-derived phosphepines (e.g., **2**) as asymmetric nucleophilic catalysts.^[7]

The use of chiral phosphines as nucleophilic catalysts for the synthesis of five-membered rings has been a focus of particular interest,^[8] due in part to the occurrence of cyclopentane subunits in a wide range of bioactive molecules,^[9] and Lu's powerful methods for convergent [3+2] annulation have been especially well-explored.^[10,11] With regard to the enantioselective construction of quaternary stereocenters,^[12] nearly all reports have described the generation of spirocyclic structures.^[8,13,14]

One complication in some of these [3+2] reactions is the formation of regioisomeric products.^[10] In 2010, Tong described a complementary [4+1] annulation, which combines structural features of the three-carbon partners in Lu's [3+2] reactions (allenoates and Morita–Baylis–Hillman derivatives) in a four-carbon partner [Eq. 1].^[15] Such a [4+1] approach obviates the formation of regioisomeric products.^[16,17]

As part of an ongoing program to demonstrate the utility and the versatility of asymmetric nucleophilic catalysis,^[18] we embarked on the development of an enantioselective variant of this [4+1] annulation. At the point that we completed our study,^[19] we were not aware of any progress by others toward this objective. However, this year Lu has described asymmetric reactions that furnish spirocyclic products in good ee [Eq. 2],^[20] which has prompted us to disclose our independent investigation. Herein, we report the first use of biphenyl-derived phosphepines (**3** and **4**) as enantioselective nucleophilic catalysts, specifically, their application in [4+1] annulations that generate cyclopentenones that bear non-spirocyclic, fully substituted stereocenters (either all-carbon or heteroatom-substituted; Eq. 3).^[21,22]

(1)

(2)

(3)

Upon determining that an array of chiral 1,1'-binaphthyl-derived phosphepines that we have reported to be useful in other nucleophile-catalyzed processes^[5] are not sufficiently effective in a model [4+1] annulation (the coupling of benzoylacetonitrile with an allenolate; Table 1, entries 1–3), we chose to synthesize and examine the utility of *biphenyl*-derived phosphepines. We were pleased to determine that new chiral phosphines **3** and **4** afford the desired cyclopentene bearing a quaternary stereocenter in high ee and yield (entries 4 and 5).^[23] If the catalyst loading is decreased to 5%, the reaction does not proceed to completion after 24 hours (entry 6). The annulation is also slower in the absence of Cs_2CO_3 and when

Cs_2CO_3 is replaced with 2,6-lutidine (entries 7 and 8). Slightly lower enantioselectivity and/or yield are observed at room temperature or when a different ester is attached to the allene (benzyl rather than benzhydryl; entries 9 and 10). The presence of two equivalents of water is deleterious for the coupling (entry 11), whereas adventitious moisture and oxygen have a relatively small impact (entry 12).^[24]

Next, we investigated the scope of this new method, catalyzed by phosphine **3**, for the enantioselective synthesis of functionalized cyclopentenones that bear an all-carbon quaternary stereocenter (Table 2).^[25] A variety of α -cyano ketones are suitable nucleophilic coupling partners, furnishing the annulation product in good ee and yield. In the case of aromatic ketones, the aryl ring can be electron-rich or electron-poor (entries 2 and 3). A thienyl ketone can be employed as a reactant (entry 4), as can alkyl ketones with alkyl groups that range from primary to tertiary (entries 5–7). The scope of the process is not limited to α -cyano ketones—both α -cyano amides (including a diphenyl amide and a Weinreb amide) and an α -cyano ester serve as useful substrates (entries 8–11).^[26]

However, when we applied this method with either an α -cyano sulfone or an α -cyano phosphonate as the nucleophilic partner, the target cyclopentene was produced with moderate enantioselectivity (<80% ee). On the other hand, by employing a related biphenyl-derived phosphine (**4**) as the chiral catalyst, we were able to achieve asymmetric [4+1] annulations with improved ee, thereby enabling the efficient synthesis of enantioenriched α -cyano sulfones,^[27] phosphine oxides, and phosphonates (Table 3).

The cyclopentene products of these catalytic asymmetric [4+1] annulations are well-poised for the introduction of additional stereocenters on the five-membered ring. For example, dihydroxylation and epoxidation of the illustrated α -cyano sulfone affords two new stereocenters with high diastereoselectivity [(Eqs. 4 and 5)].

(4)

(5)

The ability to achieve enantioselective [4+1] annulations of allenates that include a substituent in the β' position would add an important dimension to the scope of this method, as the product would bear contiguous quaternary and tertiary stereocenters. In his original report, Tong provided one example of a PPh_3 -catalyzed reaction of a β' -substituted allenate (with benzoylacetonitrile; 2:1 dr).^[15] In a preliminary study, we have obtained a promising lead with an α -cyano sulfone as the nucleophile [(Eq. 6)].^[28]

(6)

To the best of our knowledge, Tong [4+1] annulations have not previously been described in the case of allenates that bear a γ substituent. We were therefore pleased to observe that phosphine **3** not only catalyzes the reaction of such a partner, it also furnishes the desired cyclopentene in good ee, diastereoselectivity, and yield [(Eq. 7)].

(7)

Tong has suggested that phosphine-catalyzed [4+1] annulations may proceed through the pathway outlined in Scheme 1.^[15] In order to gain insight into the mechanism of the reaction catalyzed by (*R*)-**3**, we determined the rate law for the coupling illustrated in Table 1; this study was conducted at room temperature without Cs_2CO_3 (under these conditions, the annulation proceeds in 89% ee and >95% yield), due to the poor solubility of Cs_2CO_3 in toluene. The rate law for this process is first order in catalyst and zeroth order in the nucleophile and the allenate. Furthermore, according to ^{31}P NMR spectroscopy, the primary resting state of the phosphine during a catalytic asymmetric annulation is not the free phosphine, but instead a phosphonium salt. Taken together, these data are consistent with the suggestion that elementary steps such as Steps 1 and 3 (Scheme 1) are unlikely to be turnover-limiting.

In summary, we have established for the first time that biphenyl-derived axially chiral phosphepines can serve as useful enantioselective nucleophilic catalysts. Specifically, we have applied these phosphines to asymmetric [4+1] annulations that provide functionalized cyclopentenes in good ee and yield. An array of either all-carbon quaternary stereocenters or fully substituted heteroatom-bearing stereocenters can be generated in this process from readily available nucleophilic partners. The synthesis of even more highly functionalized/stereochemically rich products is possible through the use of substituted allenates or through diastereoselective reactions of the product cyclopentenes. Determination of the rate law for a [4+1] annulation catalyzed by phosphepine **3** suggests that the turnover-limiting step occurs after the addition of the chiral phosphine to the allenate, and likely after the addition of the second coupling partner as well. Additional studies directed at expanding the scope of enantioselective nucleophilic catalysis by chiral phosphines are underway.
